

React is a JavaScript library for building user interfaces.

React is used to build reusable, interactive, and component-based user interfaces.

A component is a reusable part of a user interface and can be written as a function.

JSX lets developers write HTML-like markup inside JavaScript.

Props are read-only inputs passed from a parent component to a child component.

State lets a component remember information between renders.

The useState Hook returns the current state and a function to update it.

Calling a state update function causes React to render the component again.

The useEffect Hook runs side effects such as data fetching, subscriptions, or timers.

The dependency array controls when an effect runs again.

Event handlers respond to actions such as clicks, typing, and form submission.

Controlled inputs keep their value in React state.

Conditional rendering displays different UI based on a condition.

Lists are commonly rendered with the map function.

Each item in a rendered list should have a stable key.

React applications are commonly divided into small components for reuse and maintenance.

The Virtual DOM helps React update the user interface efficiently.

React does not provide a backend or database; it focuses on the user interface.

React Router is commonly used to create multiple client-side pages.

React can call an API with fetch and display the returned data.

Context can share values such as themes or authenticated users across components.
